

How to compare climate impacts of transport

J. Fuglestvedt

Thanks to

Marianne Lund, Jens Borken-Kleefeld, Keith Shine, and Terje Berntsen

Transport Emissions: The Climate Challenge
Results from IP QUANTIFY and SSA ATTICA
Brussels, 24 June 2010

Typical questions:

”How large is the climate impact of transport?”

”Should I go by car, bus, plane, ship.....?”

”... what is best for climate”?

Difficult questions to answer

- What does these questions really mean?
- Need to specify several things

Comparing climate impacts of transportation

Challenges:

Broad mix of substances and physical / chemical processes

Warming and **cooling** effects

Large **span in lifetimes** (from < hours to centuries)

→ Effects depend on location of emissions.

→ Contributions to climate change differ strongly after the time of emissions.

“measures... should be cost-effective” and
”...*cover all relevant sources, sinks and reservoirs...*”

Kyoto Protocol: made this operational by its *multi-gas approach*

Often called “basket approach”

CO_2 , CH_4 , N_2O , $HFCs$, $PFCs$, SF_6

Transportation goes beyond the Kyoto basket

NO_x , SO_2 , CO , VOC , H_2O , *contrails, cirrus*

Design of analysis of climate impacts of transport

- **Time frames**

- emissions
- responses

- **Spatial dimension**

Geographical dependence

- emissions
- responses

- **Boundaries of the analysis**

- e.g. well-to-wheel vs tank-to-wheel
- related activities

- Which **components** should be included?

- **Normalization by transport work**

(passenger-km or tonn-km)

- **Impact parameter**

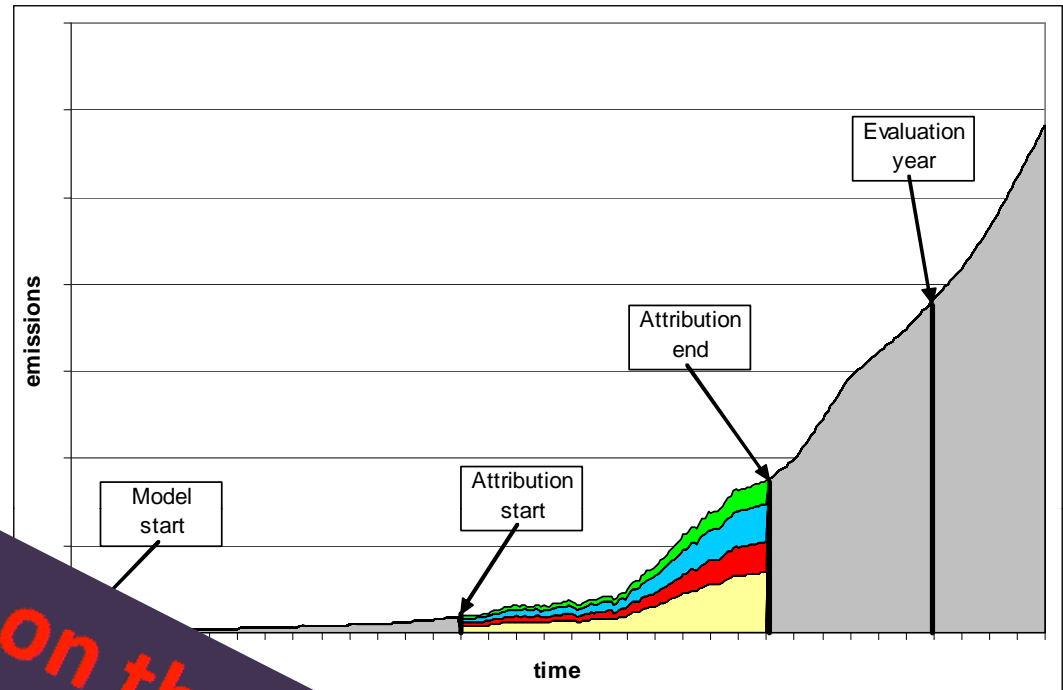

- Radiative forcing
- temperature
- sea level rise

Design of analysis of climate impacts of transport

- **Time frames**

- emissions
- responses

- **Boundaries of the analysis**

- e.g. well-to-wheel vs tailpipe
- related activities

Impact parameter
Forcing

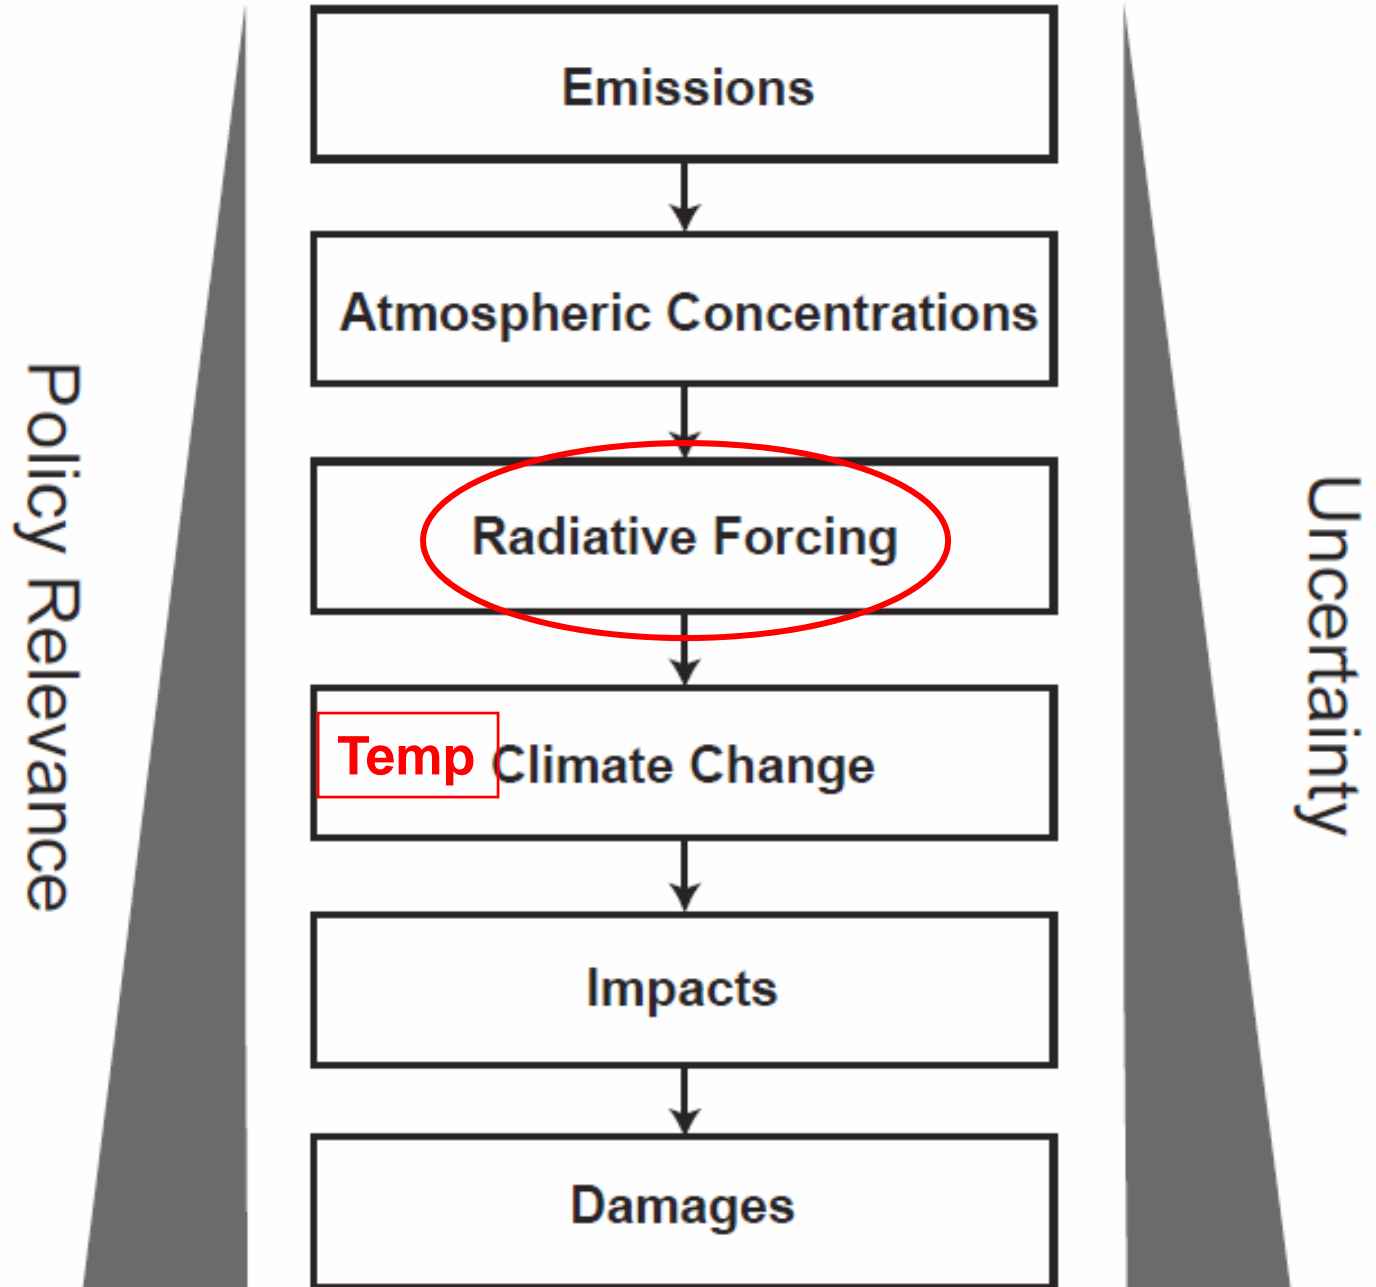

- Which **components** should be included

- **Normalization by transport work**

(passenger-km or tonn-km)

Choice of climate impact

“But climate impacts of transport should be given per transport work”

Specific climate impact = Climate impact / transport work

What is an adequate denominator?

Climate impact / person-km

Climate impact / ton-km

Climate impact / passenger-hour

Climate impact / value-km

Climate impact / volume km

More on this in presentation by Jens Borken-Kleefeld

Time frames

Effects of:

- Historical emissions (as presented by Keith Shine)
- Current annual emissions
- Emissions sustained for a period (e.g. lifetime of a car)
- Future emissions (scenarios)

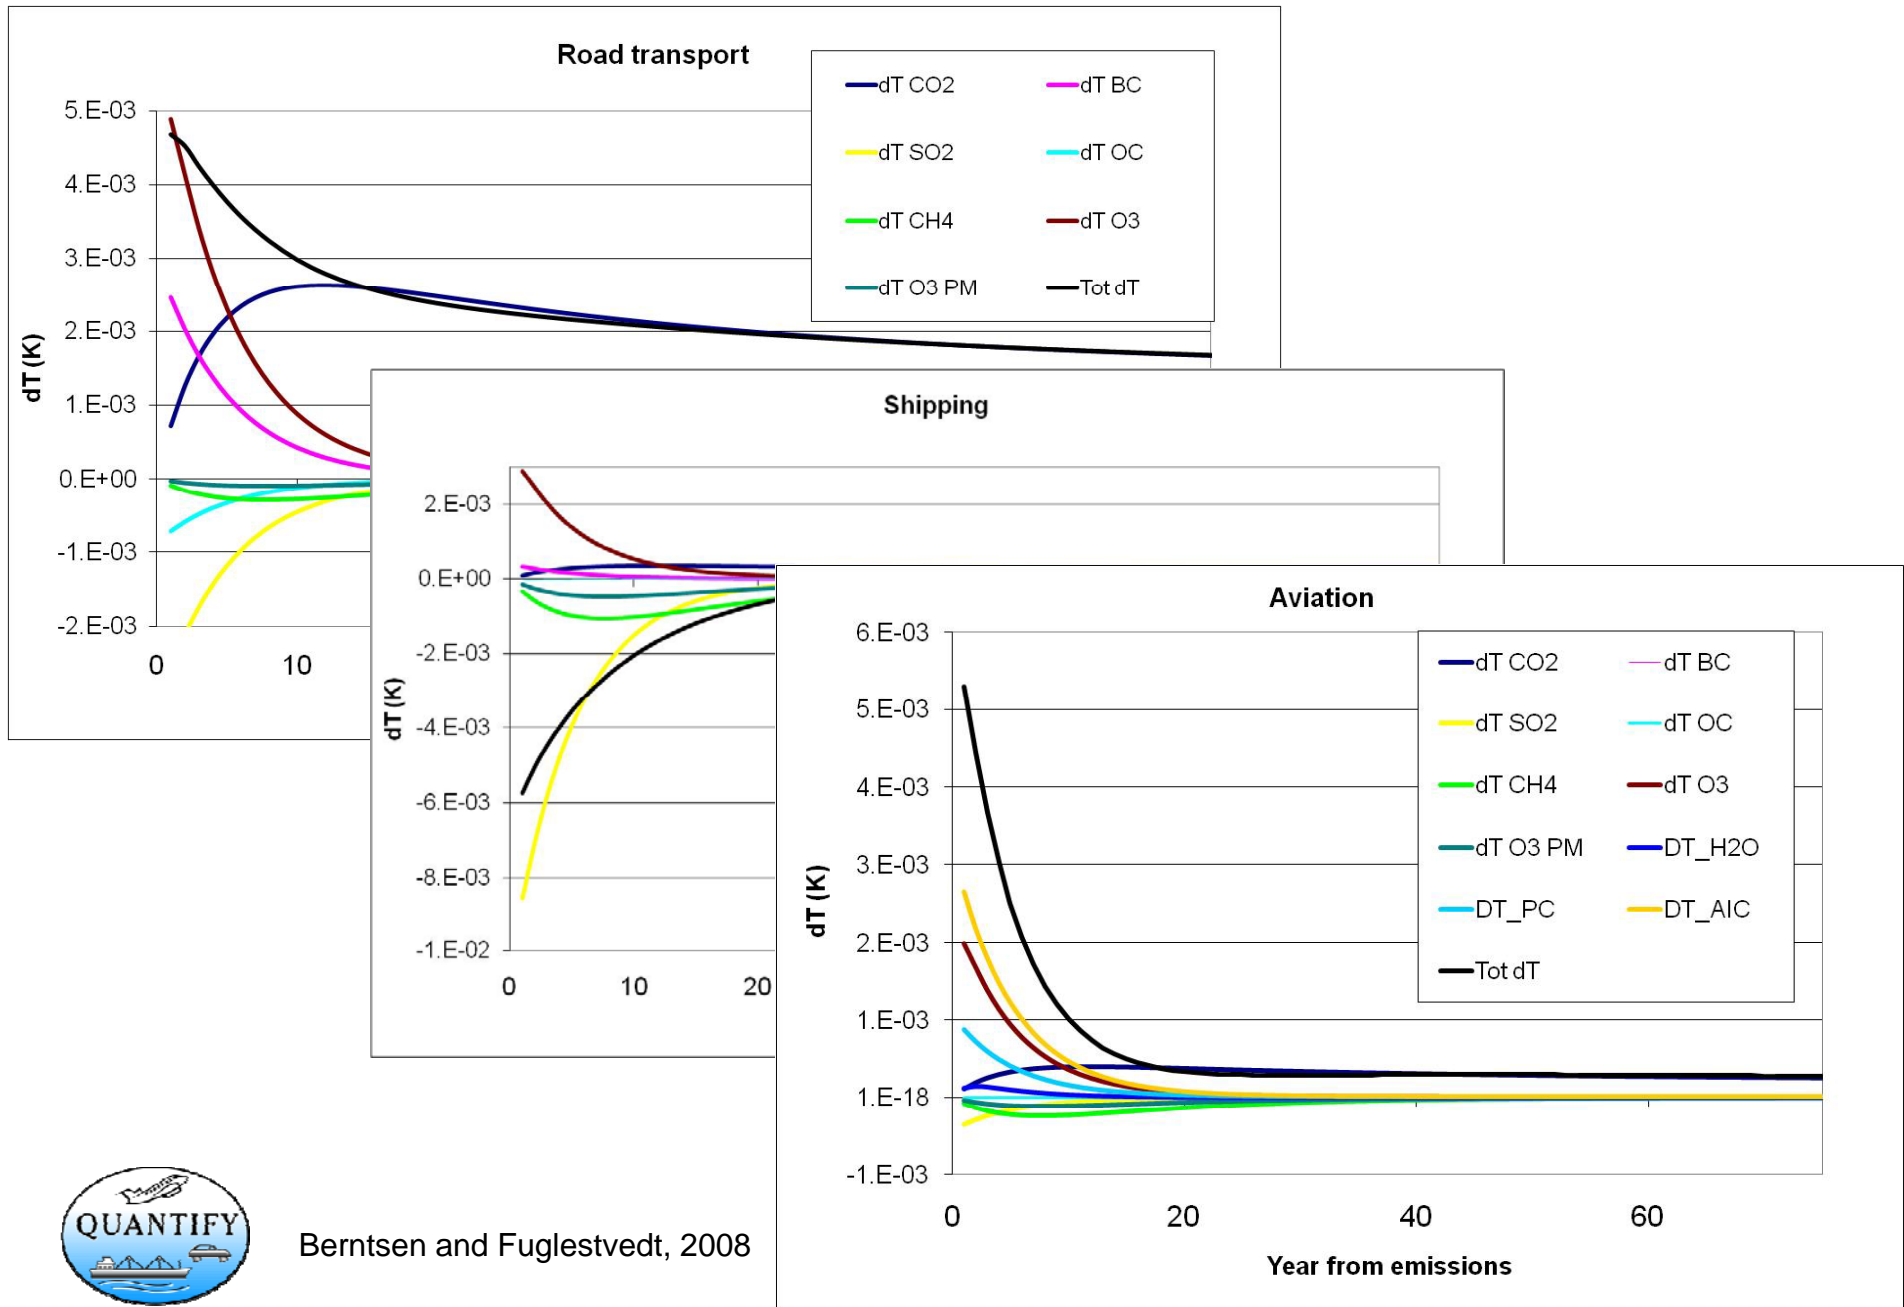

Timeframe: **Historical**

Total transport:
10% of
man-made
warming in 2000

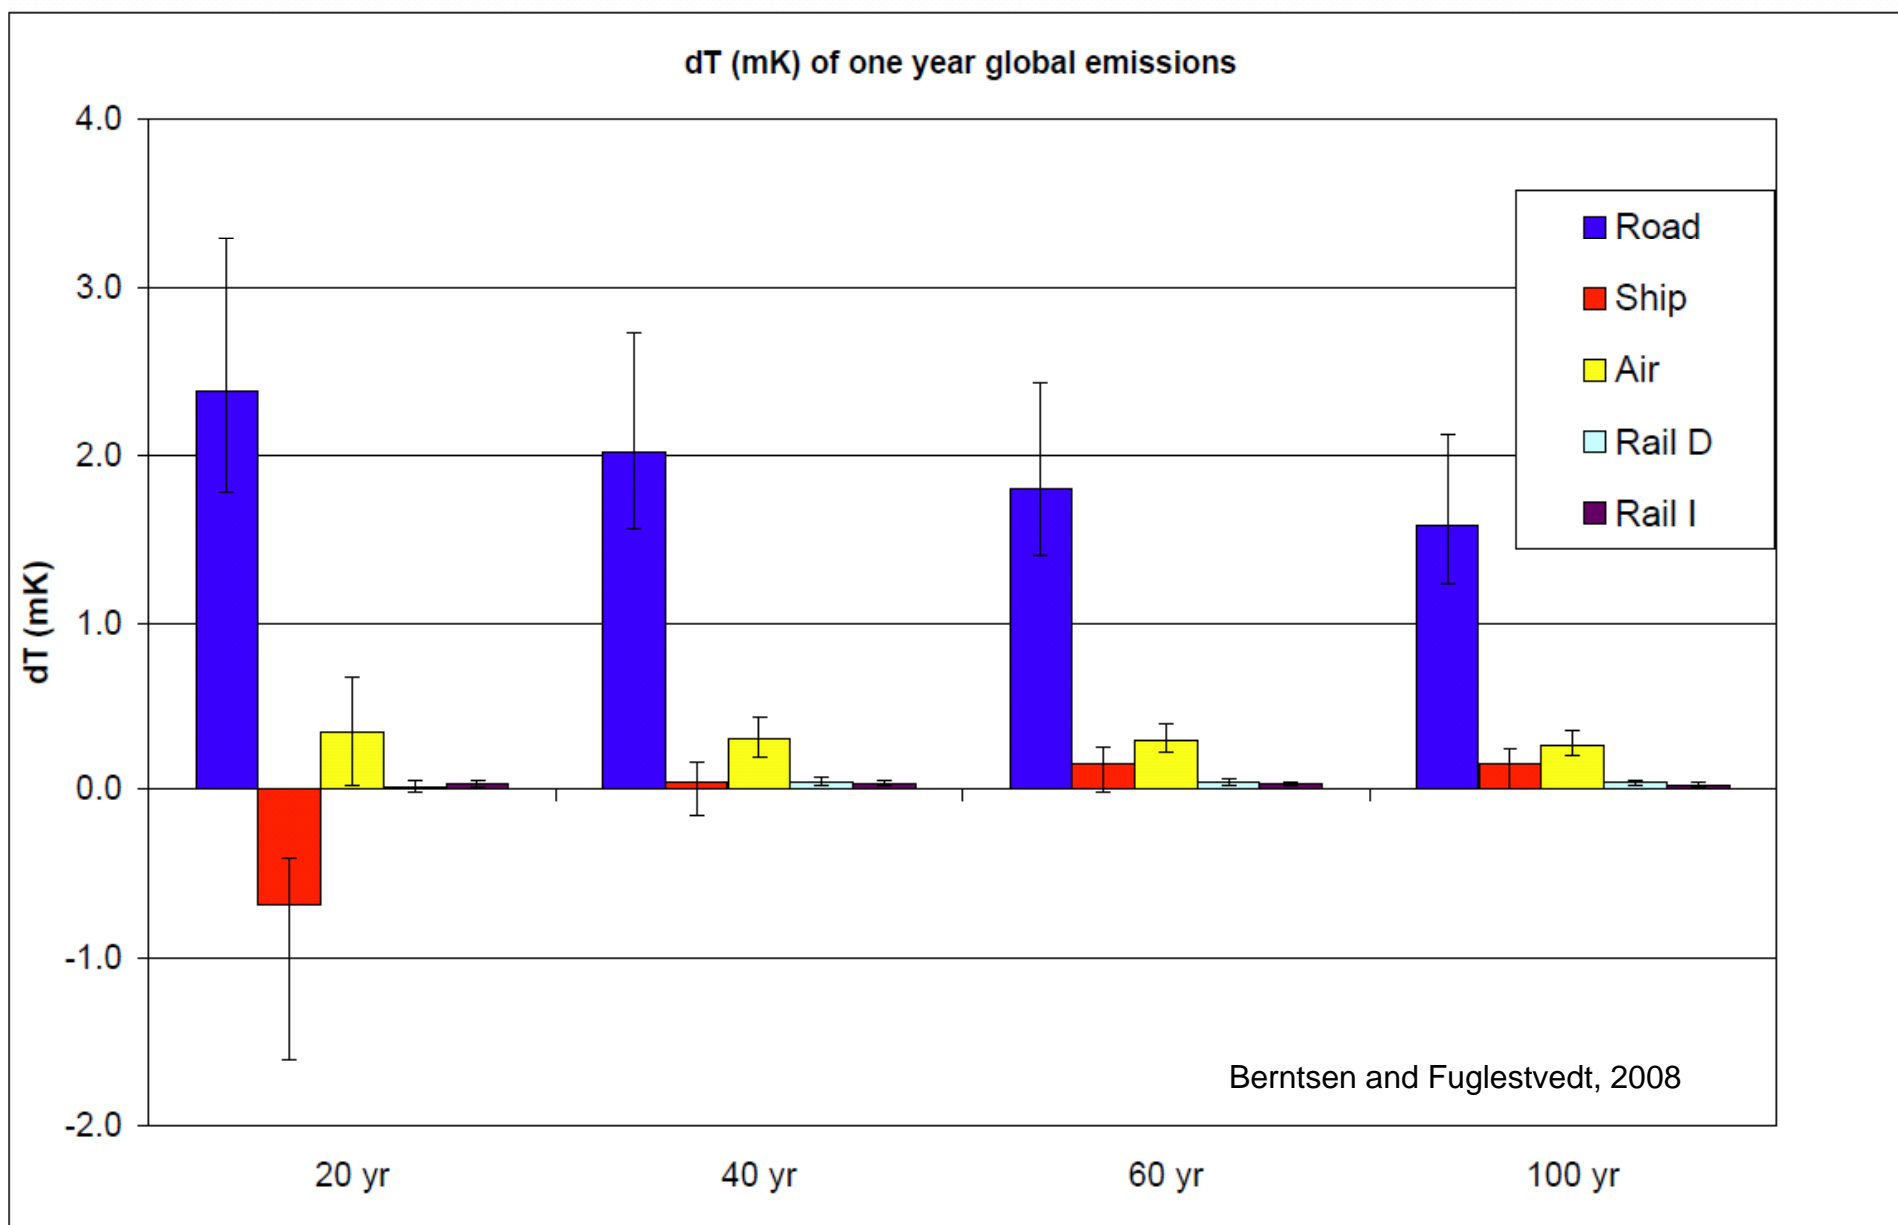

Current global emissions - one year

Berntsen and Fuglestvedt, 2008

Current global emissions – selected time horizons

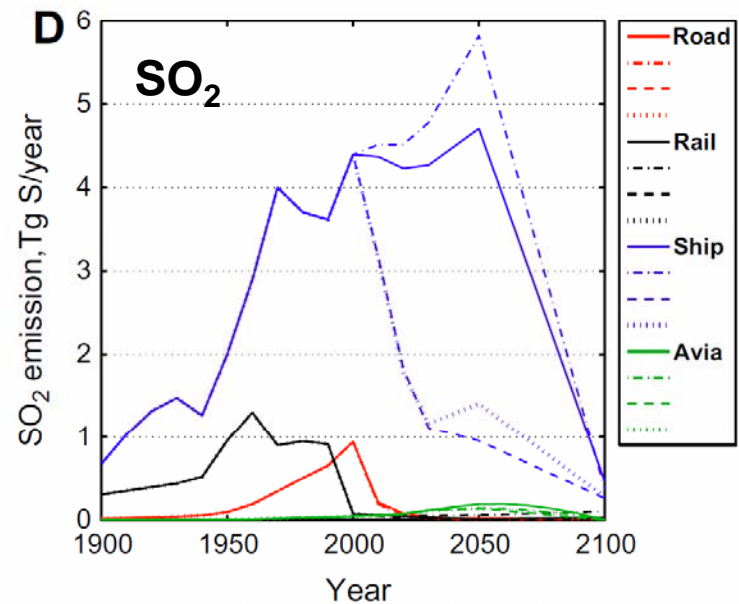

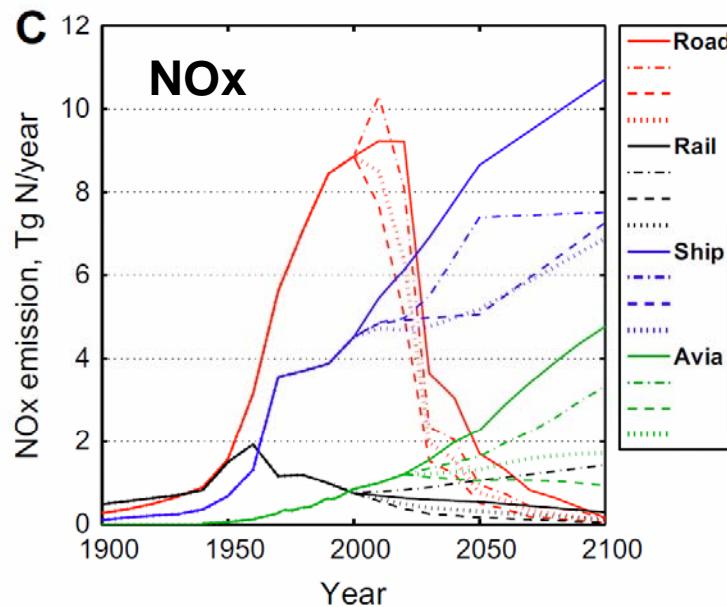

Current emissions - kept constant

Future scenarios

Emissions

- IPCC SRES storylines
- New technology
- Fuel mix
- Emission factors
- Regional developments

Borken et al., 2009;
Uherek et al., 2009;
Skeie et al., 2009

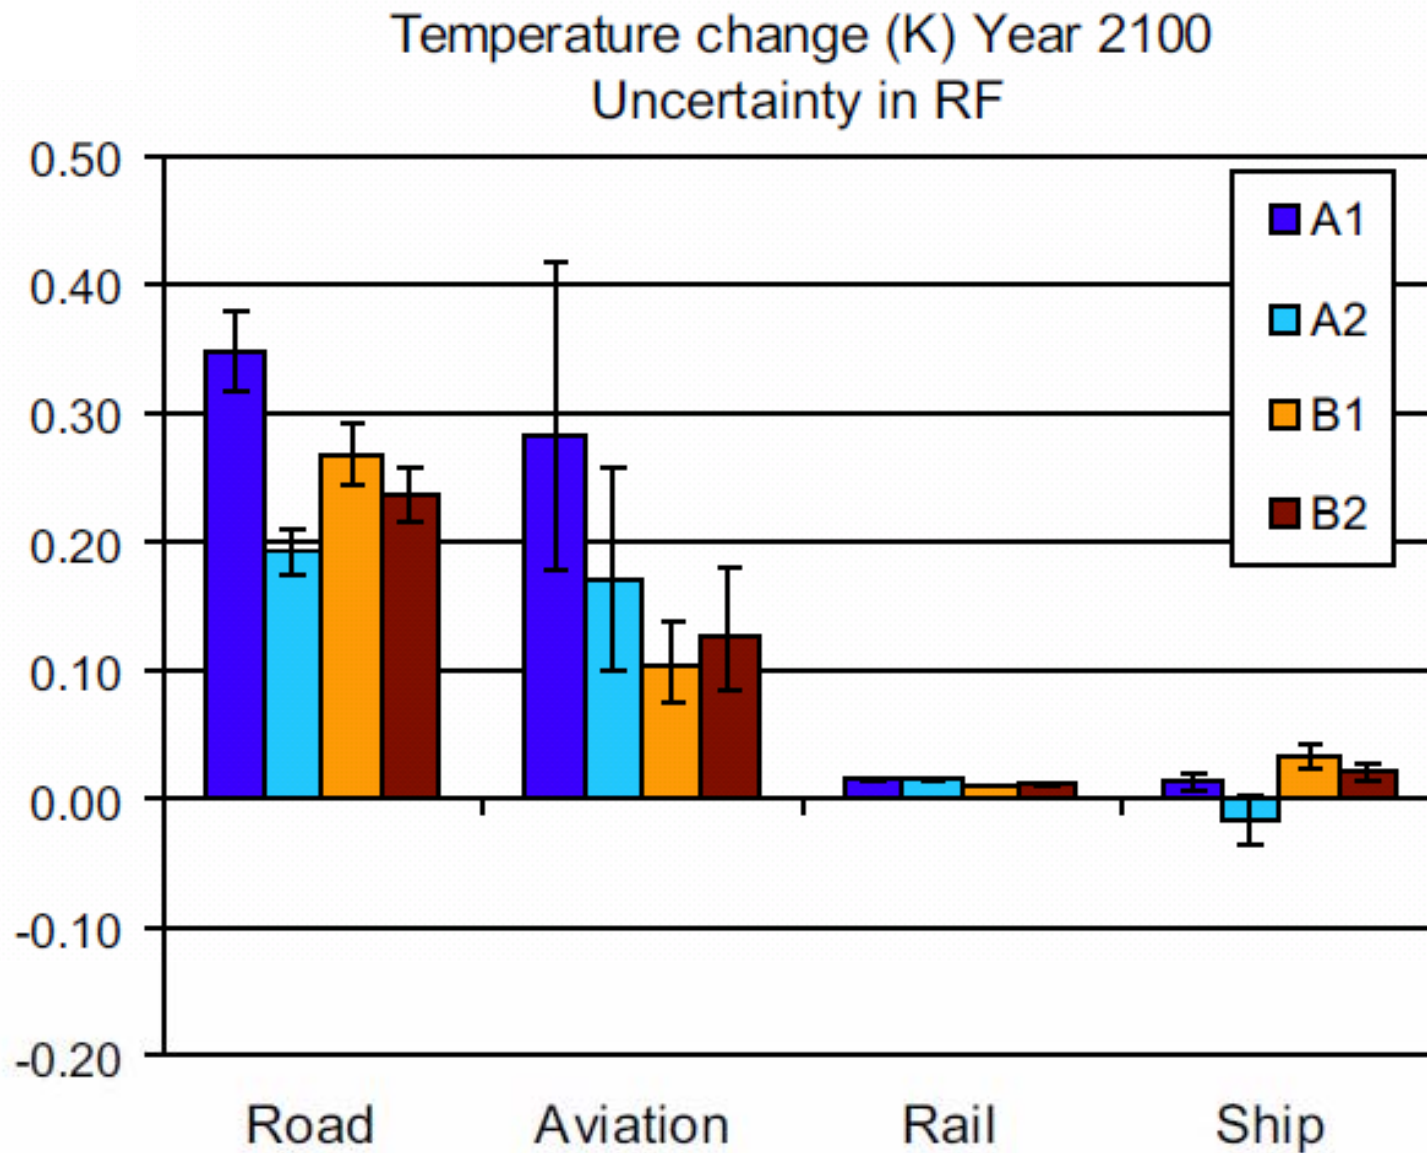

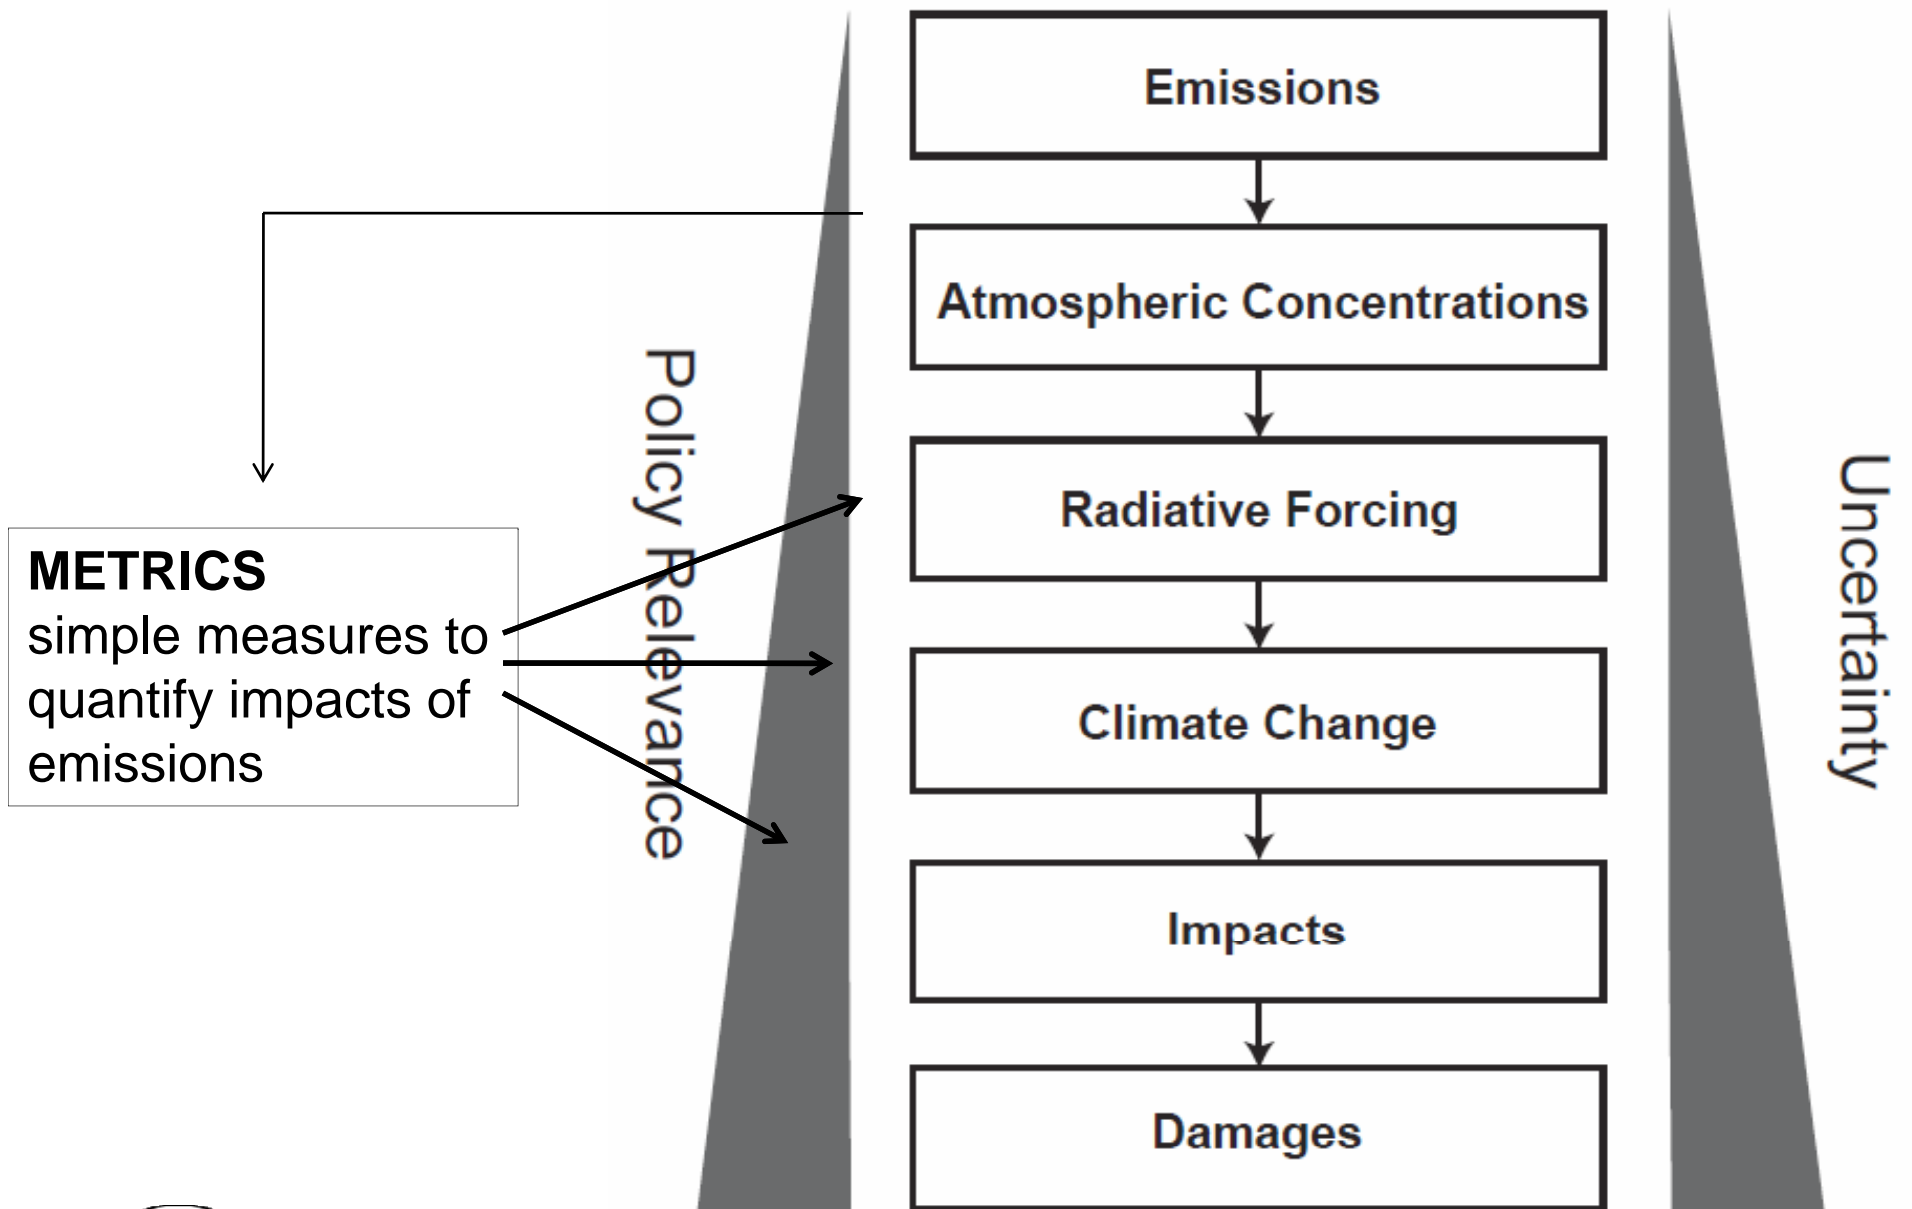

Future scenarios: Change in global mean surface temperature

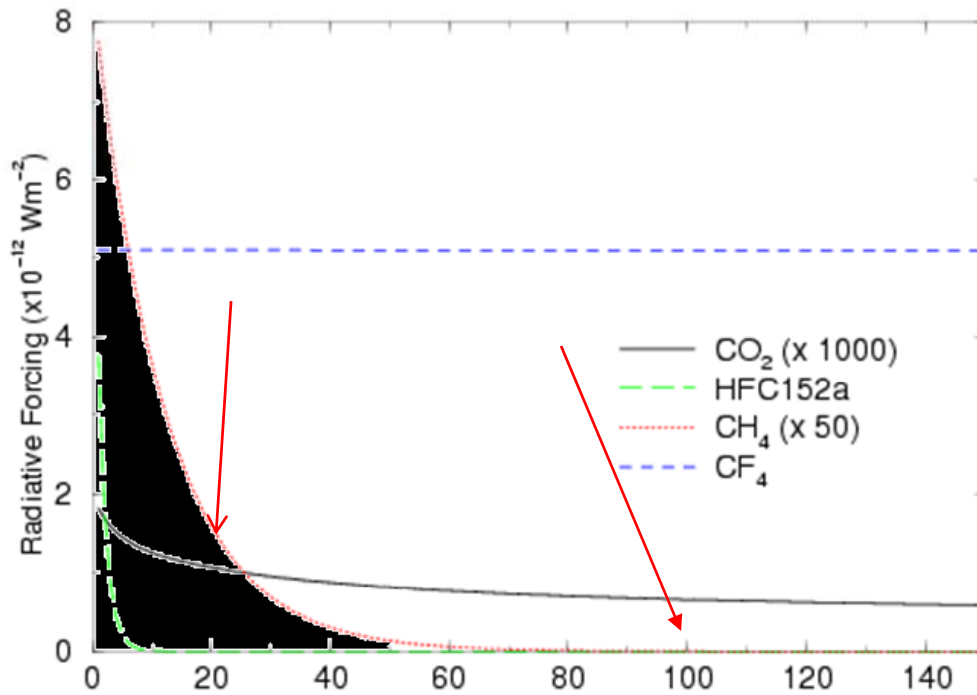

Total transport
2000: ~ 10%
2100: 10-20%

By sector in 2100
Road: 5-12%
Aviation: 4-8%

$$\text{GWP}_i(T) = \frac{\int_0^T \text{RF}_i(t) dt}{\int_0^T \text{RF}_{\text{CO}_2}(t) dt}$$

→ strong memory
(often misunderstood; no
climate response included)

$$\text{GTP}_i(t) = \frac{\Delta T_i(t)}{\Delta T_{\text{CO}_2}(t)}$$

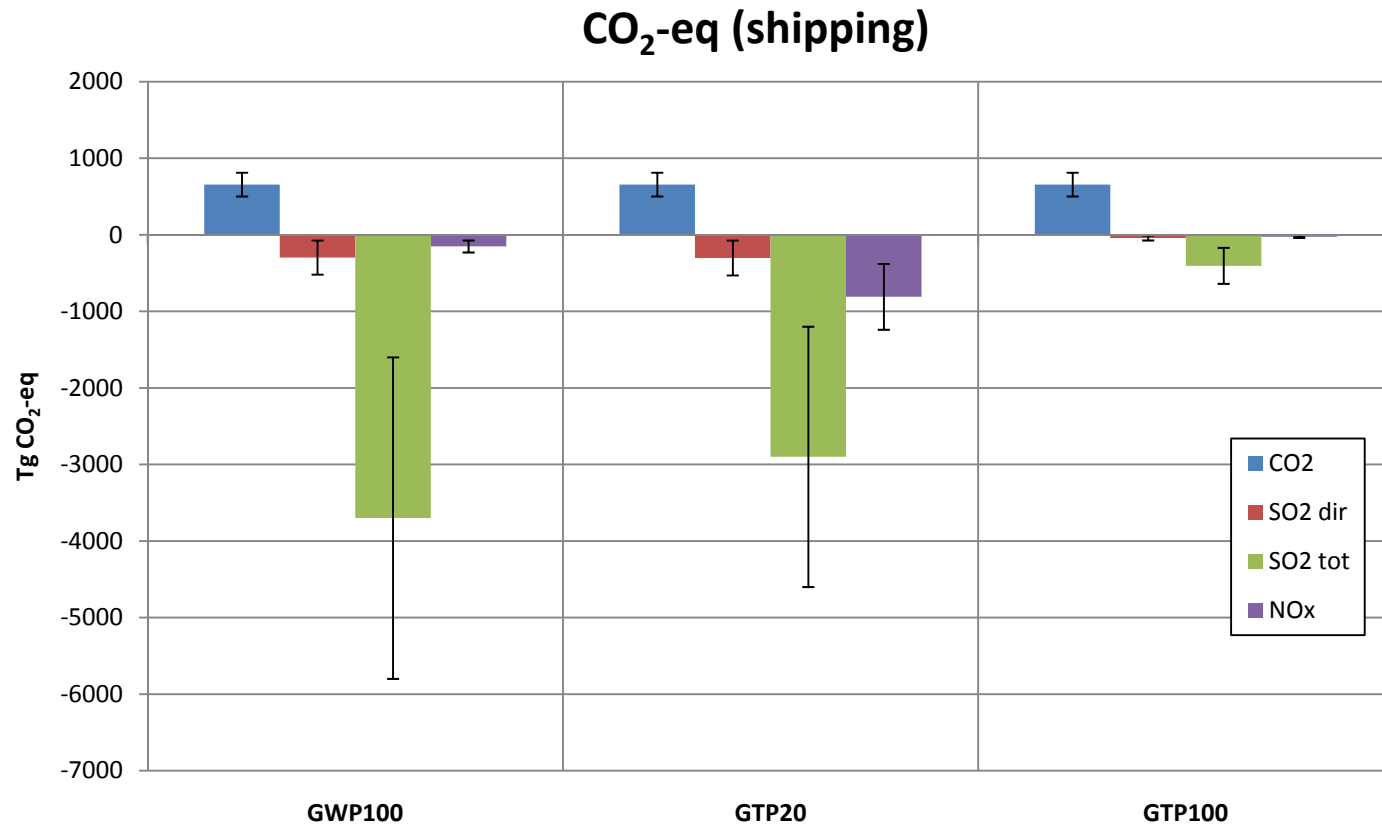

Large differences for short-lived
components (CH_4 , BC....)

AVIATION: Emissions x Metric = CO₂ equivalents (Tg / yr)

Based on Lee et al., 2009 (ATTICA)

Shipping: Emissions x Metric = CO₂ equivalents (Tg / yr)

Based on Eyring et al., 2009 (ATTICA)

Conclusions

Many different perspectives – need to clarify the questions

On a global scale:

Historically: Road transport > aviation >> train

Shipping: **cooling**

Future: Shipping: Switches from **cooling** to **warming**

Road transport: Dominating

Aviation: potentially strong short-lived effects, but large uncertainties

Alternative perspective: impact per transport work (next presentation)

Emission metrics are useful for:

- Climate protocols and emission trading
- Climate policy assessments, related effects and trade-offs

GTP and GWP are fundamentally different

One single time horizon gives a partial picture
