Statements in the Executive Summary

Working Group I (WGI) of the Intergovernmental Panel on Climate Change (IPCC) assesses the current evidence on the physical science of climate change, evaluating knowledge gained from observations, reanalyses, paleoclimate archives and climate model simulations, as well as physical, chemical and biological climate processes. This chapter sets the scene for the WGI assessment, placing it in the context of ongoing global and regional changes, international policy responses, the history of climate science and the evolution from previous IPCC assessments, including the Special Reports prepared as part of this Assessment Cycle. Key concepts and methods, relevant recent developments, and the modelling and scenario framework used in this assessment are presented.

IPCC 2021, Chap. 1

Statements in the Executive Summary

Framing and Context of the WGI Report (1)

The WGI contribution to the IPCC Sixth Assessment Report (AR6) assesses new scientific evidence relevant for a world whose climate system is rapidly changing, overwhelmingly due to human influence. The five IPCC assessment cycles since 1990 have comprehensively and consistently laid out the rapidly accumulating evidence of a changing climate system, with the Fourth Assessment Report (AR4, 2007) being the first to conclude that warming of the climate system is unequivocal. Sustained changes have been documented in all major elements of the climate system, including the atmosphere, land, cryosphere, biosphere and ocean. Multiple lines of evidence indicate the unprecedented nature of recent large-scale climatic changes in context of all human history, and that they represent a millennial-scale commitment for the slow-responding elements of the climate system, resulting in continued worldwide loss of ice, increase in ocean heat content, sea level rise and deep ocean acidification. {1.2.1, 1.3, Box 1.2, Appendix 1.A}

The central column shows the AR5 WGI chapter categories. The central column lists the AR5 WGI chapters in Figure 1.1: Large-Scale Information (purple), Process Understanding (gold),

Statements in the Executive Summary

Framing and Context of the WGI Report (2)

Since the IPCC Fifth Assessment Report (AR5), the international policy context of IPCC reports has changed. The UN Framework Convention on Climate Change (UNFCCC, 1992) has the overarching objective of preventing 'dangerous anthropogenic interference with the climate system'. Responding to that objective, the Paris Agreement (2015) established the long-term goals of 'holding the increase in global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5^{o}C above pre-industrial levels' and of achieving 'a balance between anthropogenic emissions by sources and removals by sinks of greenhouse gases in the second half of this century'. Parties to the Agreement have submitted Nationally Determined Contributions (NDCs) indicating their planned mitigation and adaptation strategies. However, the NDCs submitted as of 2020 are insufficient to reduce greenhouse gas emission enough to be consistent with trajectories limiting global warming to well below 2°C above pre-industrial levels (*high confidence*). {1.1, 1.2}

Characterizing understanding and uncertainty in assessment findings

Evaluation and communication of degree of certainty in AR6 findings

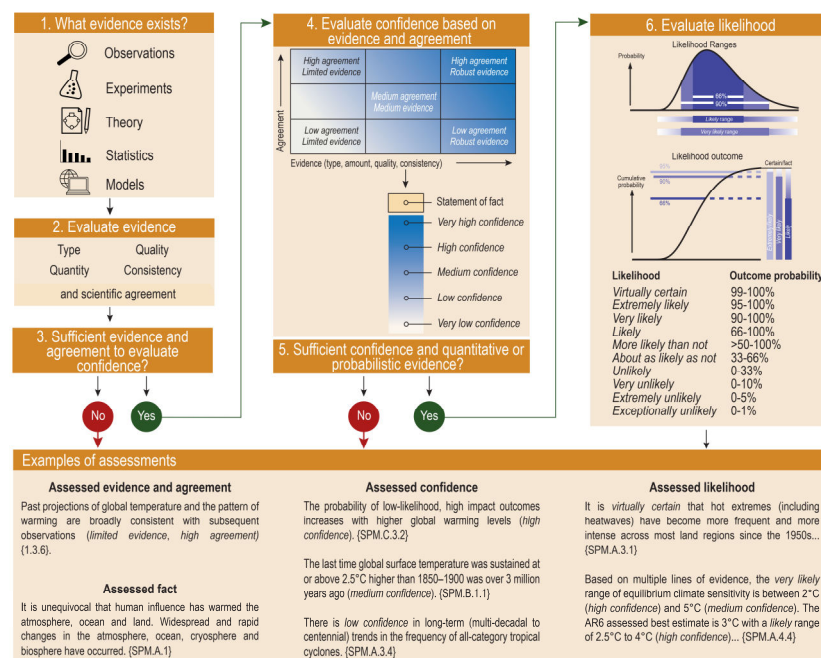

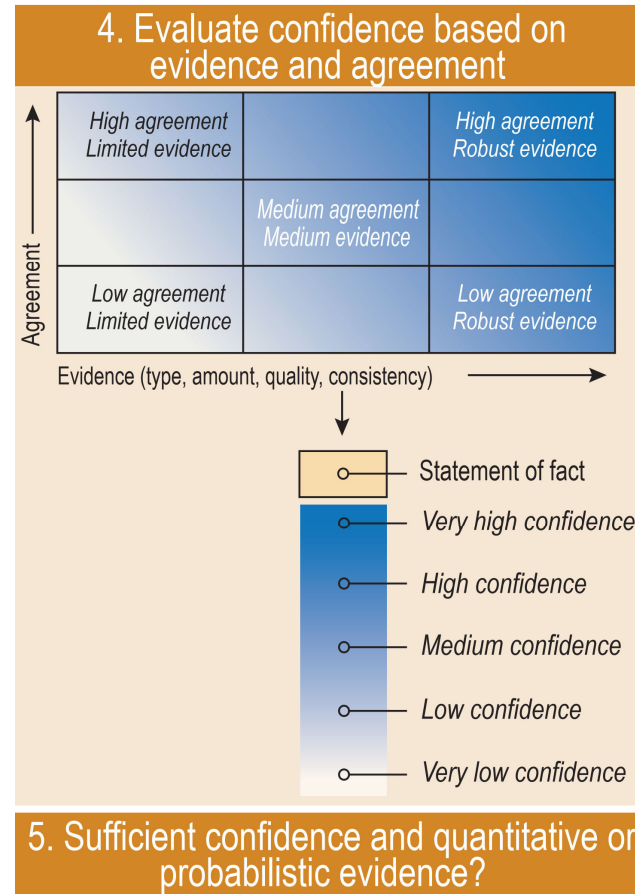

Box 1.1, Figure 1 | The IPCC AR6 approach for characterizing understanding and uncertainty in assessment findings. This diagram illustrates the step-by-step process authors use to evaluate and communicate the state of knowledge in their assessment (Mastrandrea et al., 2010). Authors present evidence/agreement, confidence, or likelihood terms with assessment conclusions, communicating their expert judgments accordingly. Example conclusions drawn from Report are presented in the box at the bottom of the figure. Figure adapted from Mach et al. (2017) .

Examples of assessments

Assessed evidence and agreement

Past projections of global temperature and the pattern of warming are broadly consistent with subsequent observations (*limited evidence*, *high agreement*) {1.3.6}.

Assessed fact

It is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred. {SPM.A.1}
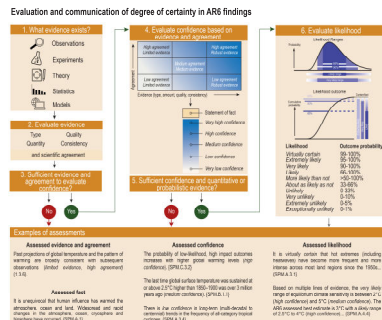

Assessed confidence

The probability of low-likelihood, high impact outcomes increases with higher global warming levels (*high confidence*). {SPM.C.3.2}

The last time global surface temperature was sustained at or above 2.5°C higher than 1850–1900 was over 3 million years ago (*medium confidence*). {SPM.B.1.1}

There is *low confidence* in long-term (multi-decadal to centennial) trends in the frequency of all-category tropical cyclones. {SPM.A.3.4}
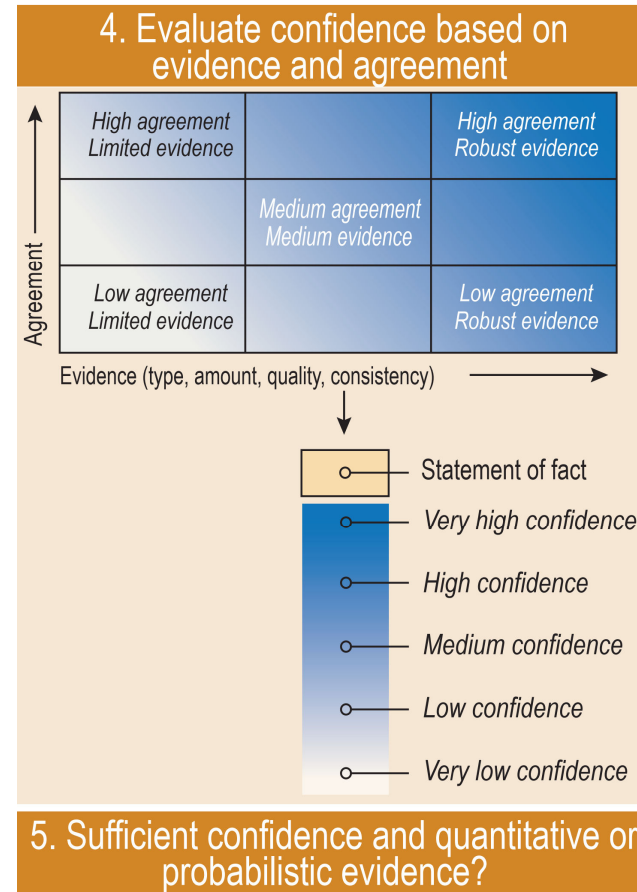

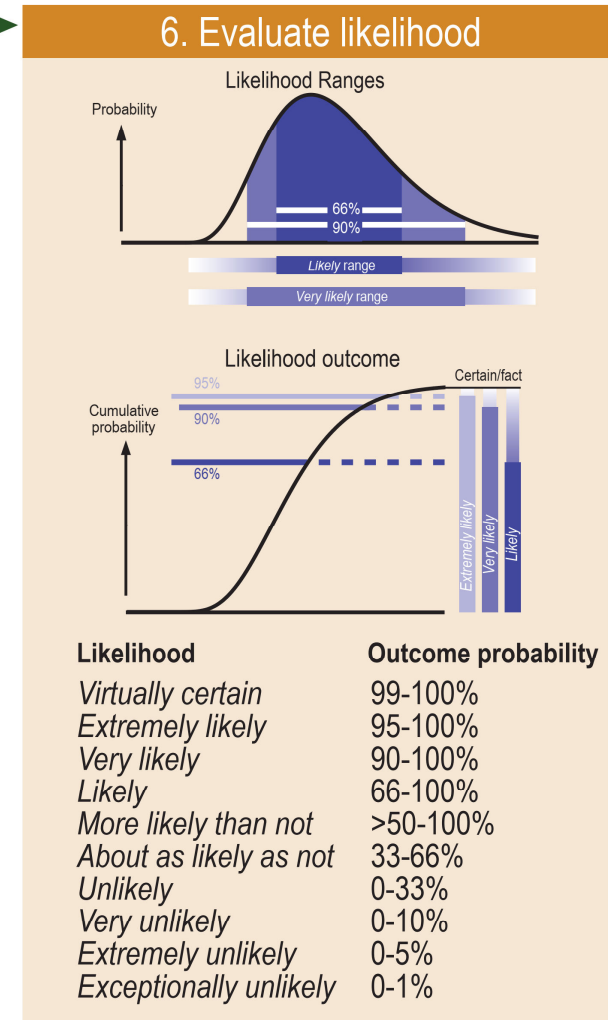

Assessed likelihood

It is *virtually certain* that hot extremes (including heatwaves) have become more frequent and more intense across most land regions since the 1950s... {SPM.A.3.1}

Based on multiple lines of evidence, the *very likely* range of equilibrium climate sensitivity is between 2°C (*high confidence*) and 5°C (*medium confidence*). The AR6 assessed best estimate is 3°C with a *likely* range of 2.5°C to 4°C (*high confidence*)... {SPM.A.4.4}

Statements in the Executive Summary

Framing and Context of the WGI Report (3)

This report provides information of potential relevance to the 2023 global stocktake.
The 5-yearly stocktakes called for in the Paris Agreement will evaluate alignment among the Agreement's long-term goals, its means of implementation and support, and evolving global efforts in climate change mitigation (efforts to limit climate change) and adaptation (efforts to adapt to changes that cannot be avoided). In this context, WGI assesses, among other topics, remaining cumulative carbon emission budgets for a range of global warming levels, effects of long-lived and short-lived climate forcers, projected changes in sea level and extreme events, and attribution to anthropogenic climate change. {Cross-Chapter Box 1.1}

IPCC 2021, Chap. 1

Statements in the Executive Summary

Framing and Context of the WGI Report (4)

Understanding of the fundamental features of the climate system is robust and well established. Scientists in the 19th-century identified the major natural factors influencing the climate system. They also hypothesized the potential for anthropogenic climate change due to carbon dioxide (CO_2) emitted by fossil fuel combustion. The principal natural drivers of climate change, including changes in incoming solar volcanic activity, orbital cycles, and changes in global biogeochemical cycles, have been studied systematically since the early 20th century. Other major anthropogenic drivers, such as atmospheric aerosols (fine solid particles or liquid droplets), land-use change and non-CO_2 greenhouse gases, were identified by the 1970s. Since systematic scientific assessments began in the 1970s, the influence of human activity on the warming of the climate system has evolved from theory to established fact. Past projections of global surface temperature and the pattern of warming are broadly consistent with subsequent observations (*limited evidence, high agreement*), especially when accounting for the difference in radiative forcing scenarios used for making projections and the radiative forcings that actually occurred. {1.3.1 - 1.3.6}

Statements in the Executive Summary

Framing and Context of the WGI Report (5)

Global surface temperatures increased by about 0.1°C (*likely* range –0.1°C to +0.3°C, *medium confidence*) between the period around 1750 and the 1850–1900 period, with anthropogenic factors responsible for a warming of 0.0°C – 0.2°C (*likely range, medium confidence*). This assessed change in temperature before 1850–1900 is not included in the AR6 assessment of global warming to date, to ensure consistency with previous IPCC assessment reports, and because of the lower confidence in the estimate. There was *likely* a net anthropogenic forcing of 0.0 – 0.3 Wm^{-2} in 1850–1900 relative to 1750 (*medium confidence*), with radiative forcing from increases in atmospheric greenhouse gas concentrations being partially offset by anthropogenic aerosol emissions and land-use change. Net radiative forcing from solar and volcanic activity is estimated to be smaller than $\pm$ 0.1 Wm-^{2} for the same period. {Cross Chapter Box 1.2, 1.4.1, Cross Chapter Box 2.3}

Long-term context of anthropogenic climate change
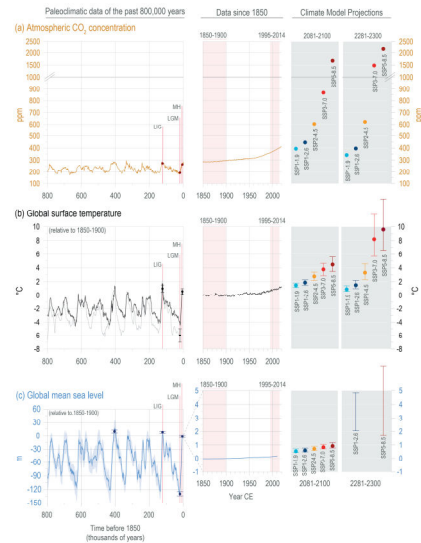

Figure 1.5 | Long-term context of anthropogenic climate change based on selected paleoclimatic reconstructions over the past 800,000 years (800 kyr) for three key indicators: atmospheric CO₂ concentrations, global mean surface temperature (GMST), and global mean sea level (GMSL).
Figure 1.5 (continued): (a) Measurements of CO₂ in air enclosed in Antarctic ice cores (Lüthi et al., 2008; Bereiter et al., 2015 [a compilation]; uncertainty ±1.3 ppm; see Sections 2.2.3 and 5.1.2 for an assessment) **and direct air measurements** (Tans and Keeling, 2020; uncertainty ±0.12 ppm). Projected CO₂ concentrations for five Shared Socio-economic Pathways (SSP) scenarios are indicated by dots on the right-hand side of each panel (grey background; (Meinshausen et al., 2020; SSPs are described in Section 1.6). **(b)** Reconstruction of GMST from marine paleoclimate proxies (light-grey line: Snyder (2016); dark grey line: Hansen et al. (2013); see Section 2.3.1 for an assessment). Observed and reconstructed temperature changes since 1850 are the AR6 assessed mean (referenced to 1850–1900; Box TS.3; 2.3.1.1); dots/whiskers on the right-hand panels (grey background) indicate the projected mean and ranges of warming derived from Coupled Model Intercomparison Project Phase 6 (CMIP6) SSP-based (2081–2100) and Model for the Assessment of Greenhouse Gas Induced Climate Change (MAGICC7; 2300) simulations (Tables 4.5 and 4.9). **(c)** Sea level changes reconstructed from a stack of oxygen isotope measurements on seven ocean sediment cores (Spratt and Lisiecki, 2016; see Chapter 2, Section 2.3.3.3 and Chapter 9, Section 9.6.2 for an assessment). The sea level record from 1850–1900 is from Kopp et al. (2016), while the 20th century record is an updated ensemble estimate of GMSL change (Palmer et al., 2021; Sections 2.3.3.3 and 9.6.1.1). Dots/whiskers on the right-hand panels of the figure (grey background) indicate the projected median and ranges derived from SSP-based simulations (2081–2100: Table 9.9; 2300: Section 9.6.3.5). Best estimates (dots) and uncertainties (whiskers), as assessed in Chapter 2, are included in the left and middle panels for each of the three indicators and selected paleo-reference periods used in this report (CO₂: Table 2.1; GMST: Section 2.3.1.1 and Cross-Chapter Box 2.3, Table 1; GMSL: Sections 2.3.3.3 and 9.6.2. See also Cross-Chapter Box 2.1). Selected paleo-reference periods: LIG — Last Interglacial; LGM — Last Glacial Maximum; MH — mid-Holocene (Cross-Chapter Box 2.1, Table 1). The non-labelled best estimate in panel (c) corresponds to the sea level high-stand during Marine Isotope Stage 11, about 410 ka (410,000 years ago; Section 9.6.2). Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

Range of projected temperature change for 1990–2030 for various regions defined in IPCC First Assessment Report (FAR)

First Assessment Report (IPCC FAR) regional temperature projections
Figure 1.10 | Range of projected temperature change for 1990–2030 for various regions defined in IPCC First Assessment Report (FAR). The **left-hand** panel shows the FAR projections (IPCC, 1990a) for southern Europe, with the darker blue shade representing the range of projected change given for the best estimate of 1.8°C global warming by 2030 compared with pre-industrial levels, and the fainter blue shade showing the range scaled by −30% to +50% for lower and higher estimates of global warming. Blue lines show the regionally averaged observations from five global temperature gridded datasets, and blue dashed lines show the linear trends in those datasets for 1990–2020 extrapolated to 2030. Observed datasets are: HadCRUT5, Cowtan and Way, GISTEMP, Berkeley Earth and NOAA GlobalTemp. The inset map shows the definition of the FAR regions used. The **right-hand** panel shows projected temperature changes by 2030 for the various FAR regions, compared to the extrapolated observational trends, following Grose et al. (2017). Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

The radiative forcing estimates from the AR6 emulator (Cross-Chapter Box 7.1) are split into GHG, other anthropogenic (mainly aerosols and land use) and natural forcings, with the average over the 1850–1900 baseline shown for each. Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

IPCC 2021, Chap. 1

Statements in the Executive Summary

Framing and Context of the WGI Report (6)

Natural climate variability can temporarily obscure or intensify anthropogenic climate change on decadal time scales, especially in regions with large internal interannual-to-decadal variability. At the current level of global warming, an observed signal of temperature change relative to the 1850–1900 baseline has emerged above the levels of background variability over virtually all land regions (*high confidence*). Both the rate of long-term change and the amplitude of interannual (year-to-year) variability differ from global to regional to local scales, between regions and across climate variables, thus influencing when changes become apparent. Tropical regions have experienced less warming than most others, but also exhibit smaller interannual variations in temperature. Accordingly, the signal of change is more apparent in tropical regions than in regions with greater warming but larger interannual variations (*high confidence*). {1.4.2, FAQ1.2}

Figure 1.13: Simulated changes in various climate indicators under historical and RCP4.5 scenarios using the MPI ESM Grand Ensemble. The grey shading shows the 5–95% range from the 100-member ensemble. The coloured lines represent individual example ensemble members, with linear trends for the 2011–2021 period indicated by the thin dashed lines. Changes in Ocean Heat Content (OHC) over the top 2000m represents the integrated signal of global warming (left). The top row shows surface air temperature-related indicators (annual GSAT change and UK summer temperatures) and the bottom row shows Arctic sea-ice related indicators (annual ice volume and September sea ice extent). For smaller regions and for shorter time period averages the variability increases and simulated short-term trends can temporarily obscure or intensify anthropogenic changes in climate. Data from Maher et al., (2019). Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

IPCC 2021, Chap. 1

Changes in tropopause height and surface temperature
Figure3: Filtered global-mean monthly-mean near-surface temperature (panel A) and p_{LRT} (panel B) in the ECHAM GSDIO and control simulations. Data were smoothed with a 60-month moving average window; bold lines are the filtered values. The grey envelope denotes the $\pm2\sigma$ 'noise envelope' in the control run data. Dashed vertical lines indicate the times at which the GSDIO surface temperature and p_{LRT} data separate from (and remain outside) the noise envelope. For display purposes, only the first 191 years of the 300-year control run are shown.

Sausen and Santer, 2003

Observed variations in regional temperatures since 1850

FAQ 1.2: **Where is climate change most apparent?**

Temperature changes are most apparent in regions with smaller natural variations.

Estimation of:
2 standard deviations of natural year-to-year variations
1 standard deviation of natural year-to-year variations

**High latitudes** (e.g. mid-North America)

Low latitudes (e.g. Tropical South America)

Smaller trend that deviates earlier from past conditions
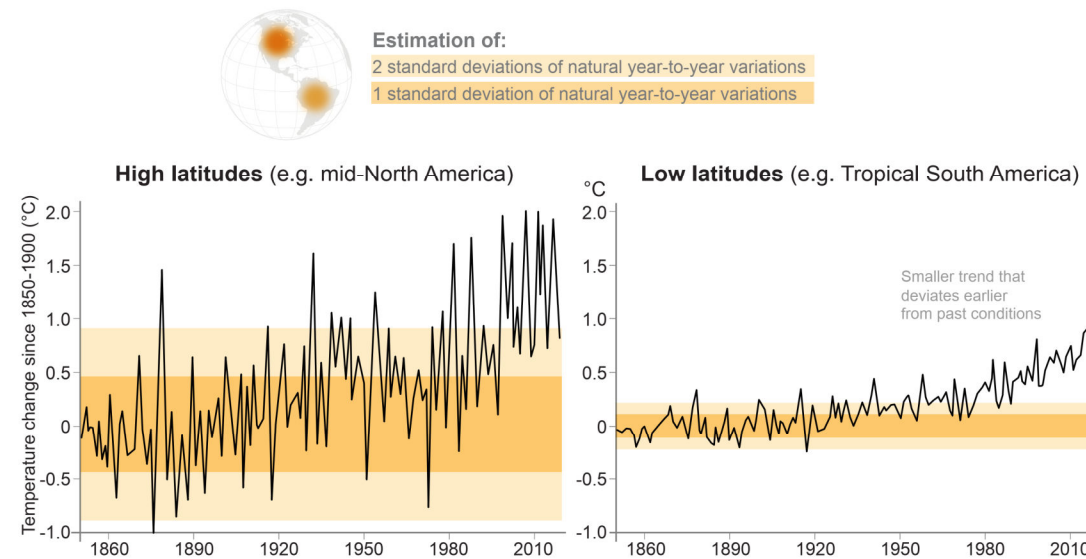

FAQ 1.2, Figure 1 | Observed variations in regional temperatures since 1850 (data from Berkeley Earth). Regions in high latitudes, such as mid-North America (40°N–64°N, 140°W–60°W, **left**), have warmed by a larger amount than regions at lower latitudes, such as tropical South America (10°S–10°N, 84°W–16°W, **right**), but the natural variations are also much larger at high latitudes (darker and lighter shading represents 1 and 2 standard deviations, respectively, of natural year-to-year variations). The signal of observed temperature change emerged earlier in tropical South America than mid-North America even though the changes were of a smaller magnitude. (Note that those regions were chosen because of the longer length of their observational record; see Figure 1.14 for more regions).

IPCC 2021, Chap. 1

Observed variations in regional temperatures since 1850

FAQ 1.2: **Where is climate change most apparent?**

Temperature changes are most apparent in regions with smaller natural variations.

Estimation of:
2 standard deviations of natural year-to-year variations
1 standard deviation of natural year-to-year variations

High latitudes (e.g. mid-North America)

Low latitudes (e.g. Tropical South America)

Smaller trend that deviates earlier from past conditions

The 'cascade of uncertainties' in CMIP6 projections

Cascade of uncertainties in climate projections
Different sources of uncertainty dominate the total uncertainty in projections for different variables, regions and time periods
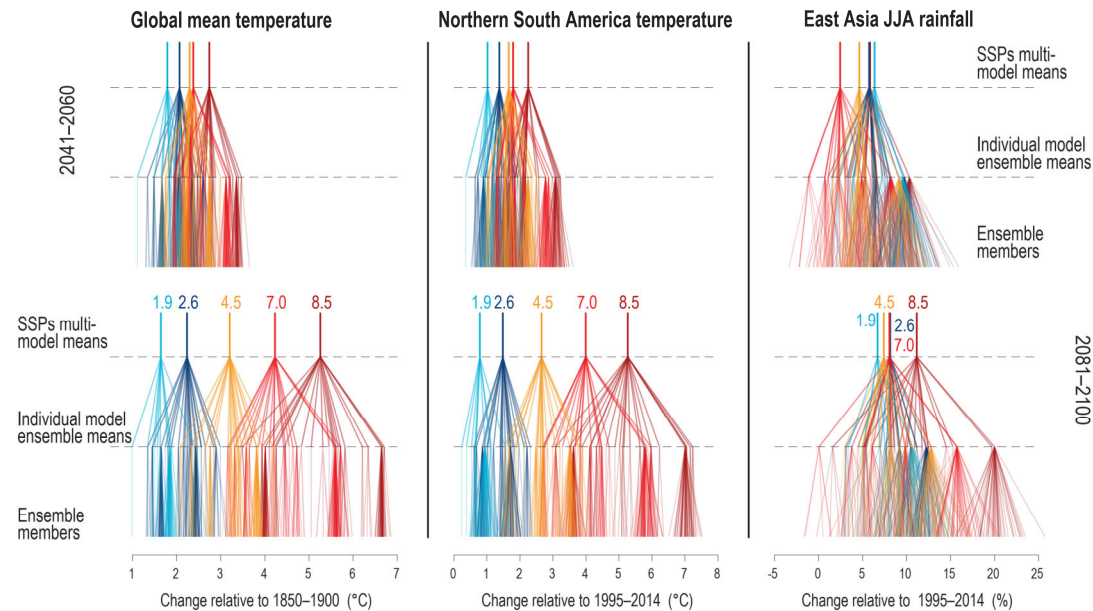

Figure 1.15 | The 'cascade of uncertainties' in CMIP6 projections. Changes in: GSAT **(left)**; Northern South America temperature **(middle)**; and East Asia summer (June–July–August, JJA) precipitation **(right)**. These are shown for two time periods: 2041–2060 **(top)** and 2081–2100 **(bottom)**. The SSP–radiative forcing combination is indicated at the top of each cascade at the value of the multi-model mean for each scenario. This branches downwards to show the ensemble mean for each model, and further branches into the individual ensemble members, although often only a single member is available. These diagrams highlight the relative importance of different sources of uncertainty in climate projections, which varies for different time periods, regions and climate variables. See Section 1.4.5 for the definition of the regions used. Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

Statements in the Executive Summary

Framing and Context of the WGI Report (7)

The AR6 has adopted a unified framework of climate risk, supported by an increased focus in WGI on low-likelihood, high-impact events. Systematic risk framing is intended to aid the formulation of effective responses to the challenges posed by current and future climatic changes and to better inform risk assessment and decision-making. AR6 also makes use of the 'storylines' approach, which contributes to building a robust and comprehensive picture of climate information, allows a more flexible consideration and communication of risk, and can explicitly address low-likelihood, high-impact events. {1.1.2, 1.4.4, Cross-Chapter Box 1.3}

Illustrating concepts of low-likelihood scenarios

Figure 1.16 | Illustrating concepts of low-likelihood outcomes. Left: schematic likelihood distribution consistent with the IPCC AR6 assessments that equilibrium climate sensitivity (ECS) is *likely* in the range 2.5°C to 4.0°C, and *very likely* between 2.0°C and 5.0°C (Chapter 7). ECS values outside the assessed *very likely* range are designated low-likelihood outcomes in this example (light grey). **Middle** and **right-hand columns:** additional risks due to climate change for 2020–2090 using the Reasons For Concern (RFCs, see IPCC, 2014b), specifically RFC1 describing the risks to unique and threatened systems and RFC3 describing risks from the distribution of impacts (O'Neill et al., 2017b; Zommers et al., 2020). The projected changes of GSAT used are the 95%, median and 5% assessed ranges from Chapter 4 for each SSP (top, middle and bottom); these are designated High ECS, Mid-range ECS and Low ECS respectively. The 'burning-ember' risk spectrum of graduated colours is usually associated with levels of committed GSAT change; instead, this illustration associates the risk spectrum with the GSAT temperature reached in each year from 2020 to 2090. Note that this illustration does not include the vulnerability aspect of each SSP scenario. Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

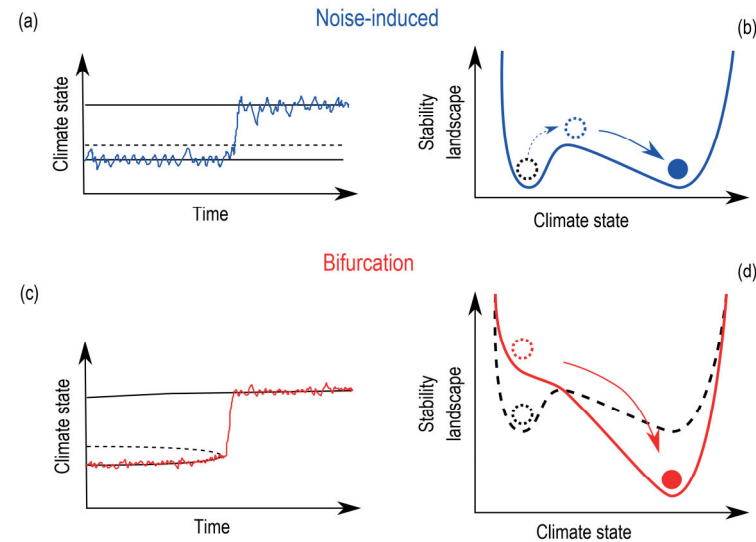

IPCC 2021, Chap. 1
Illustration of two types of tipping points: noise-induced and bifurcation

Figure 1.17 | Illustration of two types of tipping points: noise-induced (a, b) and bifurcation (c, d). (a) and **(c)** are example time-series (coloured lines) through the tipping point, with solid-black lines indicating stable climate states (e.g., low or high rainfall) and dashed lines representing the boundary between stable states. **(b)** and **(d)** are stability landscapes, which provide an intuitive understanding of the different types of tipping point. The 'valleys' represent different climate states the system can occupy, with 'hilltops' separating the stable states. The resilience of a climate state is implied by the depth of the valley. The current state of the system is represented by a ball. Both scenarios assume that the ball starts in the left-hand valley (dashed-black lines) and then through different mechanisms dependent on the type of tipping transitions to the right-hand valley (coloured lines). Noise-induced tipping events (a, b), for instance drought events causing sudden dieback of the Amazon rainforest, develop from fluctuations within the system. The stability landscape in this scenario remains fixed and stationary. A series of perturbations in the same direction, or one large perturbation, are required to force the system over the hilltop and into the alternative stable state. Bifurcation tipping events (c, d), such as a collapse of the thermohaline circulation in the Atlantic Ocean under climate change, occur when a critical level in the forcing is reached. Here the stability landscape is subjected to a change in shape. Under gradual anthropogenic forcing the left-hand valley begins to shallow and eventually vanishes at the tipping point, forcing the system to transition to the right-hand valley.

Statements in the Executive Summary

Framing and Context of the WGI Report (8)

The construction of climate change information and communication of scientific understanding are influenced by the values of the producers, the users and their broader audiences. Scientific knowledge interacts with pre-existing conceptions of weather and climate, including values and beliefs stemming from ethnic or national identity, traditions, religion or lived relationships to land and sea (*high confidence*). Science has values of its own, including objectivity, openness and evidence-based thinking. Social values may guide certain choices made during the construction, assessment and communication of information (*high confidence*). {1.2.3, Box 1.1}

IPCC 2021, Chap. 1

15.11.2023

Choice of baseline matters
when comparing observations and model simulations

**Global temperature variations and baseline choices**
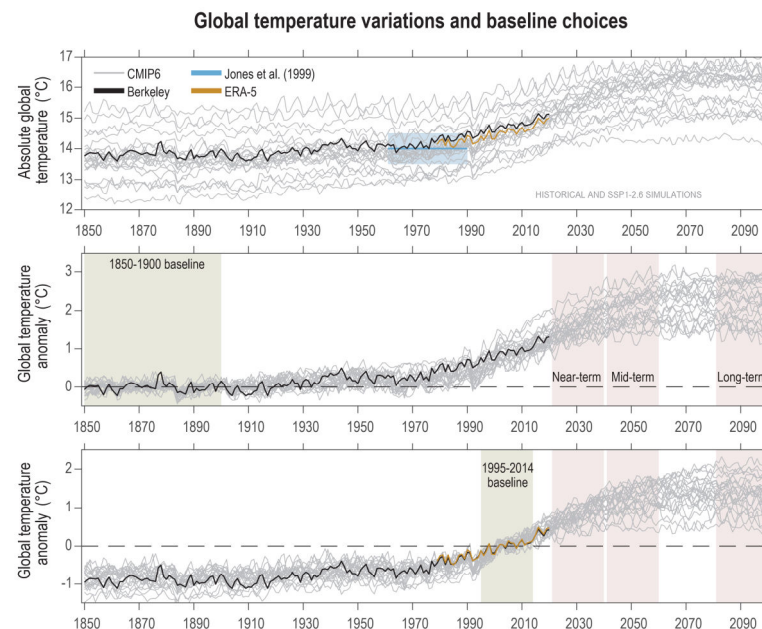

Figure 1.11 | Choice of baseline matters when comparing observations and model simulations. Global mean surface air temperature (GSAT, grey) from a range of CMIP6 historical simulations (1850–2014; 25 models) and SSP1-2.6 (2015–2100) using absolute values **(top)** and anomalies relative to two different baselines: 1850–1900 **(middle)** and 1995–2014 **(bottom)**. An estimate of GSAT from a reanalysis (ERA-5, orange, 1979–2020) and an observation-based estimate of global mean surface air temperature (GMST) (Berkeley Earth, black, 1850–2020) are shown, along with the mean GSAT for 1961–1990 estimated by Jones et al. (1999), light blue shading (14.0°C ± 0.5°C). Using the more recent baseline (bottom) allows the inclusion of datasets which do not include the periods of older baselines. The middle and bottom panels have scales which are the same size but offset. Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

**Data, Tools and Methods Used across the WGI Report (1)**

Capabilities for observing the physical climate system have continued to improve and expand overall, but some reductions in observational capacity are also evident (*high confidence*). Improvements are particularly evident in ocean observing networks and remote-sensing systems, and in paleoclimate reconstructions from proxy archives. However, some climate-relevant observations have been interrupted by the discontinuation of surface stations and radiosonde launches, and delays in the digitisation of records. Further reductions are expected to result from the COVID-19 pandemic. In addition, paleoclimate archives such as mid-latitude and tropical glaciers as well as modern natural archives used for calibration (e.g., corals and trees) are rapidly disappearing owing to a host of pressures, including increasing temperatures (*high confidence*). {1.5.1}
Temporal coverage of selected instrumental climate observations (top) and selected paleoclimate archives (bottom)

Statements in the Executive Summary

Data, Tools and Methods Used across the WGI Report (2)

Reanalyses have improved since AR5 and are increasingly used as a line of evidence in assessments of the state and evolution of the climate system (*high confidence*).
Reanalyses, where atmosphere or ocean forecast models are constrained by historical observational data to create a climate record of the past, provide consistency across multiple physical quantities and information about variables and locations that are not directly observed. Since AR5, new reanalyses have been developed with various combinations of increased resolution, extended records, more consistent data assimilation, estimation of uncertainty arising from the range of initial conditions, and an improved representation of the ocean. While noting their remaining limitations, the WGI report uses the most recent generation of reanalysis products alongside more standard observation-based datasets. {1.5.2, Annex 1}

Sausen, Klimaänderung 1.1

IPCC 2021, Chap. 1

15.11.2023

Statements in the Executive Summary

Data, Tools and Methods Used across the WGI Report (3)

Since AR5, new techniques have provided greater confidence in attributing changes in climate extremes to climate change. Attribution is the process of evaluating the relative contributions of multiple causal factors to an observed change or event. This includes the attribution of the causal factors of changes in physical or biogeochemical weather or climate variables (e.g., temperature or atmospheric CO_2) as done in, or of the impacts of these changes on natural and human systems (e.g., infrastructure damage or agricultural productivity), as done in WGII. Attributed causes include human activities (such as emissions of greenhouse gases and aerosols, or land-use change), and changes in other aspects of the climate, or natural or human systems. {Cross-WG Box 1.1}

Sausen, Klimaänderung 1.1

15.11.2023

Statements in the Executive Summary

Data, Tools and Methods Used across the WGI Report (4)

The latest generation of complex climate models has an improved representation of physical processes, and a wider range of Earth system models now represent biogeochemical cycles. Since the AR5, higher-resolution models that better capture smaller-scale processes and extreme events have become available. Key model intercomparisons supporting this assessment include the Coupled Model Intercomparison Project Phase 6 (CMIP6) and the Coordinated Regional Climate Downscaling Experiment (CORDEX), for global and regional models respectively.

15.11.2023

**Data, Tools and Methods Used across the WGI Report (4)**

The latest generation of complex climate models has an improved representation of physical processes, and a wider range of Earth system models now represent biogeochemical cycles. Since the AR5, higher-resolution models that better capture smaller-scale processes and extreme events have become available. Key model intercomparisons supporting this assessment include the Coupled Model Intercomparison Project Phase 6 (CMIP6) and the Coordinated Regional Climate Downscaling Experiment (CORDEX), for global and regional models respectively. Results using CMIP Phase 5 (CMIP5) simulations are also assessed. Since the AR5, large ensemble simulations, where individual models perform multiple simulations with the same climate forcings, are increasingly used to inform understanding of the relative roles of internal variability and forced change in the climate system, especially on regional scales. The broader availability of ensemble model simulations has contributed to better estimations of uncertainty in projections of future change (*high confidence*). A broad set of simplified climate models is assessed and used as emulators to transfer climate information across research communities, such as for evaluating impacts or mitigation pathways consistent with certain levels of future warming. {1.4.2, 1.5.3, 1.5.4, Cross-chapter Box 30 7.1}

A world map showing the increased diversity of modelling centres contributing to CMIP and CORDEX
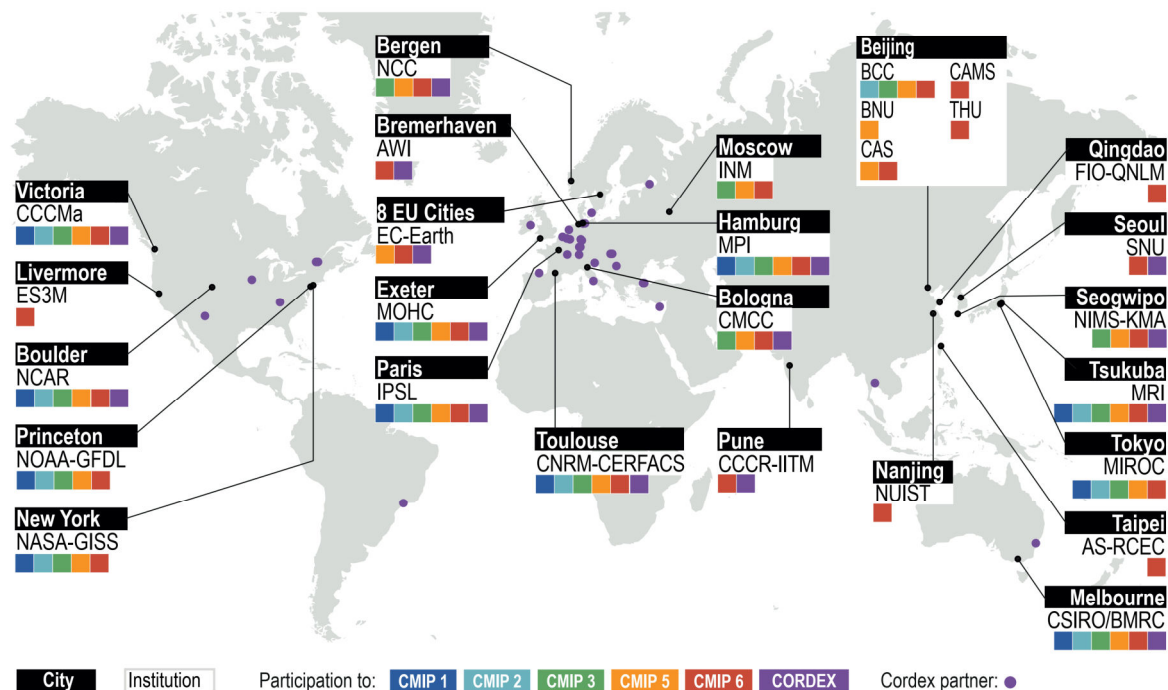

Figure 1.20 | World map showing the increased diversity of modelling centres contributing to CMIP and CORDEX. Climate models are often developed by international consortia. One such consortium, EC-Earth, is shown as an example under the label **8 EU Cities** (involving SMHI, Sweden; KNMI, The Netherlands; DMI, Denmark; AEMET, Spain; Met Éireann, Ireland; CNR-ISAC, Italy; Instituto de Meteorologia, Portugal; and FMI, Finland). There are too many such collaborations to display all of them on this map. More complete information about institutions contributing to CORDEX and CMIP6 is found in Annex II.

Resolution of the atmospheric and oceanic components of global climate models participating in CMIP5, CMIP6, and HighResMIP

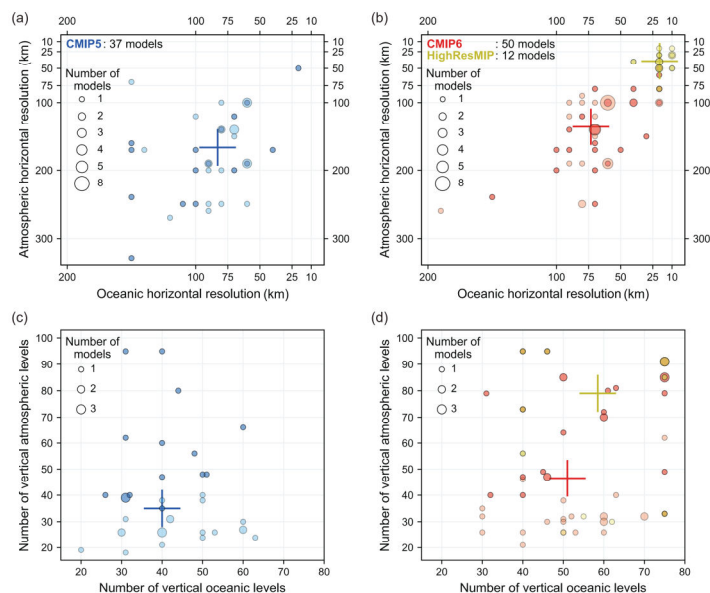

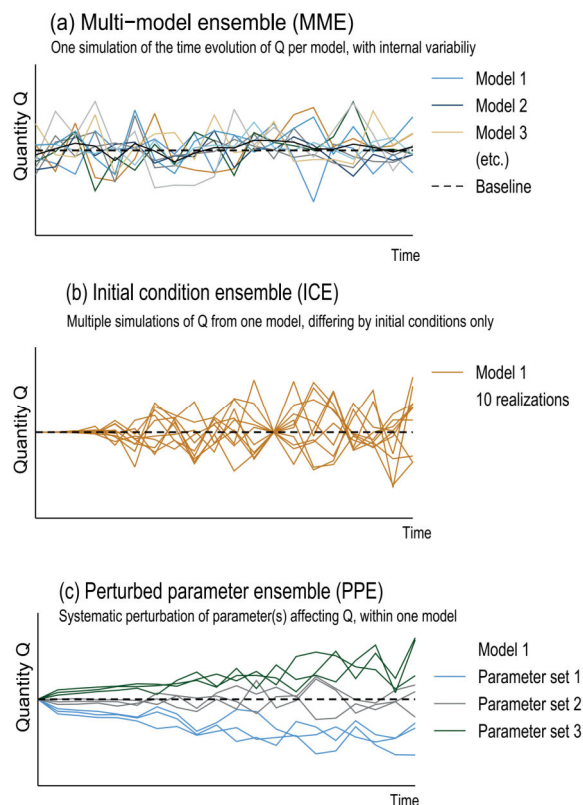

Figure 1.19 | Resolution of the atmospheric and oceanic components of global climate models participating in CMIP5, CMIP6 and HighResMIP: (a, b) horizontal resolution (km), and (c, d) number of vertical levels. Darker-colour circles indicate high-top models (in which the top of the atmosphere is above 50 km). The crosses are the median values. These models are documented in Annex II. Note that duplicated models in a modelling group are counted as one entry when their horizontal and vertical resolutions are the same. For HighResMIP, one atmosphere–ocean coupled model with the highest resolution from each modelling group is used. The horizontal resolution (rounded to 10 km) is the square root of the surface area of the Earth divided by the number of grid points, or the area of the ocean surface divided by the number of surface ocean grid points, for the atmosphere and ocean, respectively.

Illustration of common types of model ensemble, simulating the time evolution of a quantity Q

(a) Multi−model ensemble (MME)
One simulation of the time evolution of Q per model, with internal variabiliy

(b) Initial condition ensemble (ICE)
Multiple simulations of Q from one model, differing by initial conditions only

(c) Perturbed parameter ensemble (PPE)
Systematic perturbation of parameter(s) affecting Q, within one model

Figure 1.21 | Illustration of common types of model ensemble, simulating the time evolution of a quantity Q (such as global mean surface temperature). **(a)** Multi-model ensemble, where each model has its own realization of the processes affecting Q, and its own internal variability around the baseline value (dashed line). The multi-model mean (black) is commonly taken as the ensemble average. **(b)** Initial condition ensemble, where several realizations from a single model are compared. These differ only by minute ('micro') perturbations to the initial conditions of the simulation, such that over time, internal variability will progress differently in each ensemble member. **(c)** Perturbed physics ensemble, which also compares realizations from a single model, but where one or more internal parameters that may affect the simulations of Q are systematically changed to allow for a quantification of the impact of those quantities on the model results. Additionally, each parameter set may be taken as the starting point for an initial condition ensemble. In this figure, each set has three ensemble members.

Statements in the Executive Summary

Data, Tools and Methods Used across the WGI Report (5)

Assessments of future climate change are integrated within and across the three IPCC Working Groups through the use of three core components: scenarios, global warming levels, and the relationship between cumulative carbon emissions and global warming. Scenarios have a long history in the IPCC as a method for systematically examining possible futures. A new set of scenarios, derived from the Shared Socio-economic Pathways (SSPs), is used to synthesize knowledge across the physical sciences, impact, and adaptation and mitigation research. The core set of SSP scenarios used in the WGI report, SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0 and SSP5-8.5, cover a broad range of emission pathways, including new low-emissions pathways. The feasibility or likelihood of individual scenarios is not part of this assessment, which focuses on the climate response to possible, prescribed emission futures. Levels of global surface temperature change (global warming levels), which are closely related to a range of hazards and regional climate impacts, also serve as reference points within and across IPCC Working Groups. Cumulative carbon emissions, which have a nearly linear relationship to increases in global surface temperature, are also used. {1.6.1-1.6.4, Cross-Chapter Box 1.5, Cross-Chapter Box 11.1}

The Dimensions of Integration across Chapters and Working Groups in the IPCC AR6 assessment
Figure 1.24 | The dimensions of integration across chapters and Working Groups in the IPCC AR6 Assessment. This Report adopts three explicit dimensions of integration to integrate knowledge across chapters and Working Groups. The first dimension is scenarios; the second dimension is global mean warming levels relative to pre-industrial levels; and the third dimension is cumulative CO_2 emissions. For the scenarios, illustrative 2100 end-points are also indicated (white circles). Further details on data sources and processing are available in the chapter data table (Table 1.SM.1).

Sample elements of climate understanding, observations and models as assessed in the IPCC First Assessment Report (1990) and Sixth Assessment Report (2021)

FAQ 1.1, Figure 1 | Sample elements of climate understanding, observations and models as assessed in the IPCC First Assessment Report (1990) and Sixth Assessment Report (2021). Many other advances since 1990, such as key aspects of theoretical understanding, geological records and attribution of change to human influence, are not included in this figure because they are not readily represented in this simple format. Fuller explanations of the history of climate knowledge are available in the introductory chapters of the IPCC Fourth and Sixth assessment reports.

IPCC 2021, Chap. 1

FAQ 1.1: **Do we understand climate change better than when the IPCC started?**

Yes. Between 1990 and 2021, observations, models and climate understanding improved, while the dominant role of human influence in global warming was confirmed.
